Syllabus

- 1. Introduction
 - Survival data
 - Censoring mechanism
 - Application in medical field
- 2. Concepts and definitions
 - Survival function
 - Hazard function
- 3. Non-parametric approach
 - Life table
 - Kaplan-Meier survival estimate
 - Hazard function
 - Median and percentile survival time
- 4. Hypothesis testing
 - Overview hypothesis, test statistics, p-values
 - Log-rank
 - Wilcoxon
 - Gehan test
- 5. Study design and sample size estimation
 - Overview
 - Survival sample size estimation
 - Accrual time and Study duration

- 6. Semiparametric model proportional hazard model
 - Partial likelihood
 - Inference
 - Time varying covariates
 - Stratification
- 7. Model checking in the PH model
 - Model checking
 - Residuals
- 8. Parametric model
 - Parametric proportional hazard model
 - Accelerate failure model
- 9. Other topics
 - Competing risk
 - Recurrent events
 - Non-proportional hazard ratio
 - Interval censoring

Recap

- Life-table
 - Discrepancy between lecture note and SAS manual
- Confidence interval for median survival

Life-table Estimate

- Also know as the actuarial estimate
 - Used in continuous survival data
 - Grouped data similar to discrete survival time
- Divide survival data T into intervals, for the i^{th} interval
 - $t_{i-1} \le t < t_i \text{ or } [t_{i-1}, t_i) \ i = 1, ..., s$
 - The intervals may or may not be of equal length

Life-table Estimate

- Within the i^{th} interval
 - d_i , number of events
 - c_i , number of censors
 - n_i , number of subjects at risk at t_i
 - $n'_i = n_i c_i/2$, average number of subjects at the interval
- Why $n'_i = n_i c_i/2$,
- i = 1, ..., s

Life-table Estimate – Conditional Probability

- For the i^{th} interval
 - ullet Conditional probability of surviving through the i^{th} interval

$$\hat{p}_i = \frac{n_i' - d_i}{n_i'}$$

• Conditional probability of experiencing an event in the i^{th} interval

$$\hat{q}_i = 1 - \hat{p}_i = \frac{d_i}{n_i'}$$

- Why $n'_i = n_i c_i/2$,
 - Not $n_i'=n_i$, underestimate the risk \widehat{q}_i
 - Not $n_i' = n_i c_i$, overestimate the risk \hat{q}_i
 - $n_i' = n_i c_i/2$, assuming constant censoring rate

Life-table Estimate – Survival Function

- In the i^{th} interval
 - Survival function at the end of the ith interval

$$\hat{S}_L(t_0) = 1$$

$$\hat{S}_L(t_i) = \hat{S}_L(t_{i-1}) \left(1 - \frac{d_i}{n_i'} \right)$$

$$\operatorname{var}\{\hat{S}_{L}(t_{i-1})\} = \hat{S}_{L}^{2}(t_{i-1}) \sum_{j=1}^{i-1} \frac{d_{j}}{n'_{j}(n'_{j} - d_{j})}$$

$$i = 1, \dots, s$$

Life-Table – SAS Manual Notation

SAS/STAT User's Guide

Life-Table Method

The life-table estimates are computed by counting the numbers of censored and uncensored observations that fall into each of the time intervals $[t_{i-1},t_i)$, $i=1,2,\ldots,k+1$ where $t_0=0$ and $t_{k+1}=\infty$. Let n_i be the number of units that enter the interval $[t_{i-1}, t_i)$, and let d_i be the number of events that occur in the interval. Let $b_i = t_i - t_{i-1}$, and let $n_i' = n_i - w_i/2$, where w_i is the number of units censored in the interval. The effective sample size of the interval $[t_{i-1}, t_i)$ is denoted by n'_i . Let t_{mi} denote the midpoint of $[t_{i-1}, t_i)$

The conditional probability of an event in $[t_{i-1},t_i)$ is estimated by

$$\hat{q}_i = rac{d_i}{n_i'}$$

and its estimated standard error is

$$\hat{\sigma}\left(\hat{q}_{i}
ight)=\sqrt{rac{\hat{q}_{i}\hat{p}_{i}}{n_{i}'}}$$

where $\hat{p}_i = 1 - \hat{q}_i$.

The estimate of the survival function at t_i is

$$\hat{S}(t_i) = egin{cases} 1 & i=0 \ \hat{S}(t_{i-1})p_{i-1} & i>0 \end{cases}$$

defined from the events from the it internal

and its estimated standard error is

$$\hat{\sigma}\left(\hat{S}(t_i)
ight) = \hat{S}(t_i)\sqrt{\sum_{j=1}^{i-1}rac{\hat{q}_j}{n_j'\hat{p}_j}}$$

• Survival function at the end of the i^{th} interval

SAS Life Table

$$\begin{split} \hat{S}_L(t_0) &= 1 \\ \hat{S}_L(t_i) &= \hat{S}_L(t_{i-1}) \left(1 - \frac{d_i}{n_i'} \right) \\ \hat{S}_L(t_i') \end{split}$$

Confidence Interval for Median and Quantiles Survival Time

K-M Estimator Median and Quantiles

• Recall, the p^{th} quantile of the survival function is

$$S(t_p) = P(T > t_p) = p$$
$$t_p = \inf\{t: S(t_p) \le p\}$$

• So, for the K-M estimator, $\hat{S}_K(t_p)=p$

$$t_p = \inf\{t: \hat{S}_K(t_p) \le p\}$$

Recall the example of the death events from the colon cancer

Confidence Interval for Median and Quantiles Survival Time

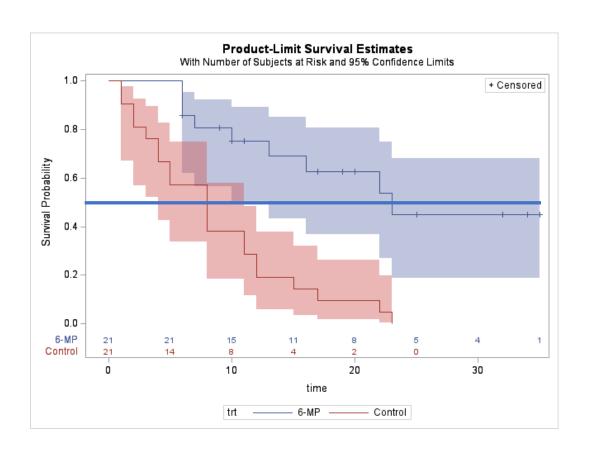

• For the K-M estimator, $\hat{S}_K(t_p) = p$

$$Var\left(\hat{S}_{K}(t_{p})\right) = \left(\frac{d\hat{S}_{K}(t_{p})}{dt_{p}}\right)^{2} var(t_{p})$$

$$= \left(-\hat{f}_{K}(t_{p})\right)^{2} var(t_{p})$$

$$var(t_{p}) = \frac{1}{\left(\hat{f}_{K}(t_{p})\right)^{2}} Var\left(\hat{S}_{K}(t_{p})\right)$$

Compare Survival Rate at 1 Year

•
$$S_{6-MP}(12) = 0.753$$
 $se(S_{6-MP}(12)) = 0.0963$
• $S_{control}(12) = 0.191$ $se(S_{control}(12)) = 0.0857$

· Test the survival rate difference

$$\frac{S_{6-MP}(12) - S_{Control}(12)}{\sqrt{se(S_{6-MP}(12))^{2} + se(S_{S_{Control}}(12))^{2}}} = \frac{0.753 - 0.191}{\sqrt{0.0963^{2} + 0.0857^{2}}} = 4.36$$

$$\sim \mathcal{N}(0/1)$$

$$p - value \le 0.001$$

Compare Two Survival Curves

• Rank based tests

Review

- Hypothesis Testing
- General parametric vs Nonparametric tests
- Background knowledge for nonparametric tests of survival data
 - 2x2 tables
 - Hypergeometric test
 - Cochran-Mantel-Haenszel (CMH) test
 - Wilcoxon rank sum test

Hypothesis Testing

- Hypothesis testing answer questions such as
 - Consider one group receive a new treatment
 - Have subjects improved after the new treatment?
 - Consider two groups
 - Group 1 new treatment
 - Group 0 placebo or control
 - Have the subjects in Group 1 became better in general than those in Group 0?
- Hypothesis testing could be
 - Parametric vs. nonparametric
 - One-sided vs. two-sided

Parametric

Distributions of the data are known

$$f(t|\theta)$$
, $\theta \in \Theta$, where

heta is a vector parameters describe the distribution of random variable T

- Θ is the parameter space
- The questions of interest can be described by distribution parameters
 - Such as mean or proportions
- The Hypotheses are set up with the parameters
 - One sample:

• 2-sided:
$$H_0$$
: $\mu = 0$ vs H_A : $\mu \neq 0$

• 1-sided:
$$H_0$$
: $\mu \le 0 \ vs$ H_A : $\mu > 0$

- Two samples
 - 2-sided: H_0 : $\mu_1 = \mu_0$ vs H_A : $\mu_1 \neq \mu_0$
 - 1-sided: H_0 : $\mu_1 \le \mu_0 \ vs \ H_A$: $\mu_1 > \mu_0$

$$Z = \frac{\hat{p}_1 - \hat{p}_2}{\hat{p}_1 + \hat{p}_2}$$

Nonparametric

- AKA: distribution-free tests
- When to use
 - Difficult to make distribution assumptions
 - · Often occurred when sample size is small
 - Data are ordinal
 - Parametric models are often used when the categories are 5 or more
 - Data are skewed
 - · Sometimes skewed data are transformed and then use parametric models
- Hypotheses
 - 1-sample 1-sided
 - H_0 : median \leq reference value vs. H_A : median > reference value
 - 2-sample 1-sided
 - H_0 : $F_1 \leq F_0 \ vs \ H_A$: $F_1 > F_0$, where F represents data distribution

Nonparametric vs. Parametric tests

Nonparametric

- 1-sample test median against a reference or targeted value
 - Sign test
 - Wilcoxon signed test require symmetric distributions such as Cauchy and uniform distributions
- 2 independent samples
 - Wilcoxon rank sum test (Mann Whitney U test)
- 2 or more independent samples
 - Kruskal-Wallis test
- Spearman correlation

Parametric

- 1-sampe t-test
 - Paired t-test
- 2-samples
 - 2-sample t-tests
 - One-way ANOVA
- 2 or more independent samples
 - One-way ANOVA
- Pearson correlation

 Consider a randomized and controlled clinical trial testing two treatments

• Group 0

- n_0 number of subjects in Group 0
- x_{01} , x_{02} , ..., x_{0n_0} observed data

• Group 1:

- n_1 number of subjects in Group 1
- $x_{11}, x_{12}, ..., x_{1n_1}$ observed data

- Rank data from the entire two groups
- Group 0
 - n_0 number of subjects in Group 0
 - x_{01} , x_{02} , ..., x_{0n_0} observed data of Group 0
 - $r_{01}, r_{02}, ..., r_{0n_0}$ ranks of Group 0 \longrightarrow get from pooled ranking
- Group 1:
 - n_1 number of subjects in Group 1
 - $x_{11}, x_{12}, \dots, x_{1n_1}$ observed data of Group 1
 - $r_{11}, r_{12}, \dots, r_{1n_1}$ ranks of Group 1

• Sum the ranks of each group

$$R_{z} = \sum_{i=1}^{n_{z}} R_{zi} \qquad z = 0, 1 - \text{group indicator}$$

$$E(R_{1}) = \frac{n_{1}(n_{1} + n_{0} + 1)}{2}$$

$$E(R_{0}) = \frac{n_{0}(n_{1} + n_{0} + 1)}{2}$$

$$Var(R_{z}) = \frac{n_{0}n_{1}(n_{1} + n_{0} + 1)}{12}$$

• The test statistics can be written as

$$\frac{R_1 - E(R_1)}{\sqrt{Var(R_1)}} \sim N(0,1)$$

· Re-write the Wilcoxon test in the Mann-Whitney test statistics

$$U_{ij} = \begin{cases} +1 & \text{if } x_{0i} > x_{1j} \\ 0 & \text{if } x_{0i} = x_{1j} \\ -1 & \text{if } x_{0i} < x_{1j} \end{cases}$$

$$U = \sum_{i=1}^{n_0} \sum_{j=1}^{n_1} U_{ij}$$

$$R_1 = \frac{n_1(n_1 + n_0 + 1)}{2} + \frac{U}{2} \quad or$$

$$U = 2R_1 - n_1(n_1 + n_0 + 1)$$

$$E(U) = 0 \quad Var(U) = \frac{n_0 n_1(n_1 + n_0 + 1)}{3}$$

$$Var(U) = 0 \quad Var(U) = \frac{n_0 n_1(n_1 + n_0 + 1)}{3}$$

$$U = 0 \quad Var(U) = \frac{n_0 n_1(n_1 + n_0 + 1)}{3}$$

• The test statistics is

Review of Hypergeometric Distribution

Nonparametric Tests for Survival Data

Nonparametric Tests for Survival Data

- Compare two groups wrt the event time distributions
 - $S_0(t)$ the control group
 - $S_1(t)$ the new treatment group
- If the occurrence of the events in the new treatment group delayed in comparison to the control group

$$H_0: S_1(t) \leq S_0(t) \text{ vs.} \qquad H_0: S_1(t) > S_0(t)$$

Log-rank Test

- AKA
 - Mantel-Haenszel test
 - Mantel-Cox test
 - Peto-Mantel-Haenszel test
- Proposed by
 - Mantel (1966)
 - Cox (1972)

- Keep in mind that survival data (T, Δ)
 - $T = \min(X, C)$
 - $\Delta = I(X < C)$
 - *X* event time
 - *C* censor time
- Group 0
 - n_0 number of subjects in Group 0
 - $(T_{01},\delta_{01}),(T_{02},\delta_{02}),\dots,(T_{0n_0},\delta_{0n_0})$,- observed survival data in Group 0
- Group 1:
 - n_1 number of subjects in Group 1
 - (T_{11},δ_{11}) , (T_{12},δ_{12}) , ..., (T_{1n_1},δ_{1n_1}) observed survival data in Group 1
- Number of events in both groups: r
 - Ordered distinct event time: $t_{(1)} < t_{(2)} < \cdots < t_{(k)}$
 - k ≤ r

- Construct $\frac{k}{2}$ 2x2 tables at each distinct event time
- At *i*th event time,
 - n_{0i} number of subjects at risk at $t_{(i)}^-$ in Group 0
 - n_{1i} number of subjects at risk at $t_{(i)}^-$ in Group 1
 - $n_i = n_{0i} + n_{1i}$ total number of subjects at risk at $t_{(i)}^-$
 - d_{0i} number of subjects at risk at $t_{(i)}$ in Group 0
 - d_{1i} number of subjects at risk at $t_{(i)}$ in Group 1
 - $d_i = d_{0i} + d_{1i}$ total number of events at $t_{(i)}$

2x2 Table at the i^{th} Event Time

| Group | Events occurred at $t_{(i)}$ | Number of subjects Survival at $t_{(i)}^+$ | Number of subject at risk at $t_{(i)}^{-}$ |
|-------|------------------------------|--|--|
| 0 | d_{0i} | $n_{0i}-d_{0i}$ | n_{0i} |
| 1 | d_{1i} | $n_{1i} - d_{1i}$ | n_{1i} |
| Total | d_i | $n_i - d_i$ | n_i |

- n_{0i} , n_{1i} , n_i are fixed at $t_{(i)}^-$
- d_i is fixed at $t_{(i)}$
- d_{0i} ~ hypergeometric distribution

Once you have doi, you can have the rest.

Hypergeometric Distribution

• Let D_{0i} be the number of events at t_{0i} in Group 0

$$P(D_{0i} = d_{0i}) = \frac{\binom{d_i}{d_{0i}}\binom{n_i - d_i}{n_{0i} - d_{0i}}}{\binom{n_i}{n_{0i}}} \qquad \text{(by proof of hypergeometric distribution)}$$

• Combination $\binom{d_i}{d_{0i}}$ - probability of selecting d_{0i} out of d_i without ordering

$$\binom{d_i}{d_{0i}} = \frac{d_i!}{d_{0i}! (d_i - d_{0i})!}$$

$$d_i! = d_i \cdot d_{i-1} \cdots 2 \cdot 1$$

2x2 Table at the i^{th} Event Time

• The mean of D_{0i}

$$e_{0i} = n_{0i}d_i/n_i$$

The expected number of events if the survival probability of the two groups are the same – the null hypothesis

ullet The difference of observed d_{0i} and the expected e_{0i}

$$d_{0i} - e_{0i}$$

Represents deviation from the null hypothesis at the i^{th} event time

The total deviation from null

$$L = \sum_{i=1}^{k} (d_{0i} - e_{0i})$$

Variance

$$\mathrm{var}(L) = var\left(\sum_{i=1}^k (d_{0i} - e_{0i})\right) \approx \sum_{i=1}^k var(d_{0i}) \quad \text{underestimate the warding}$$
 bution

From hypergeometric distribution

$$var(d_{0i}) = \frac{n_{0i}n_{1i}d_i(n_i - d_i)}{n_i^2(n_i - 1)}$$

$$var(L) = \sum_{i=1}^{k} \frac{n_{0i}n_{1i}d_{i}(n_{i}-d_{i})}{n_{i}^{2}(n_{i}-1)}$$

$$\frac{L}{\sqrt{var(L)}} \sim N(0,1)$$

positively correlated.)

• If there is no tie at each event time, log-rank test statistics reduces to

$$\frac{\sum_{i=1}^{k} (d_{0i} - n_{0i}/n_i)}{\sum_{i=1}^{k} n_{0i} n_{1i}/n_i^2}$$

where d_{0i} can be 0 or 1

The numerators of the log-rank test is the difference of the observed and expected

$$\begin{split} \left(d_{0i} - \frac{n_{0i}d_i}{n_i}\right) &= \frac{n_{0i}n_{1i}}{n_i} \left(\frac{d_{0i}}{n_{0i}} - \frac{d_{1i}}{n_{1i}}\right) \\ &= \frac{n_{0i}n_{1i}}{n_i} (h_{0i} - h_{1i}) \end{split}$$

• Like the CMH test for several 2x2 tables, the log-rank test has the optimal power when the hazard ratio is constant over time, i.e.

$$h_0(t) = \lambda h_1(t)$$
 or $S_0(t) = S_1(t)^{\lambda}$

Example: Leukemia Data

- Group 0: 6+,6,6,6,7,9+,10+,10,11+,13,16,17+,19+,20+,22,23,25+,32+,32+,34+,35+
- 2 Group 1: 1,1,2,2,3,4,4,5,5,8,8,8,11,11,12,12,15,17,22,23
 - 16 Distinct event time: 1, 2, 3, 4, 5, 6, 7, 8, 10, 11, 12, 15, 16, 17, 22, 23

| Group | Events at $t_{(i)}$ | Survival at $t_{(i)}^+$ | At risk at $t_{(i)}^-$ |
|-------|---------------------|-------------------------|------------------------|
| 0 | d_{0i} | $n_{0i}-d_{0i}$ | n_{0i} |
| 1 | d_{1i} | $n_{1i}-d_{1i}$ | n_{1i} |
| Total | d_i | $n_i - d_i$ | n_i |

| | tz | tz | ŧ; |
|-----|----|----|----|
| O | 0 | 21 | 21 |

<.0001

-2Log(LR)

The Gehan's Wilcoxon Test

• With right censored data, extending Censoring in the Wilcoxon Test

$$U_{ij} = \begin{cases} +1 & \text{if } t_{0i} > t_{1j} \text{; } \delta_{1j} = 1 \text{ at event} & \text{time} \\ 0 & \text{if } & \text{otherwise} \\ -1 & \text{if } t_{0i} < t_{1j} \text{; } \delta_{0i} = 1 \end{cases}$$

$$GW = \sum_{i=1}^{n_0} \sum_{j=1}^{n_1} U_{ij}$$

Under Null

$$E_{H_0}(GW)=0$$

$$\frac{GW}{\sqrt{Var(GW)}} \sim N(0,1)$$

The Gehan's Wilcoxon Test

- The generalized Wilcoxon procedure proposed by
 - Gehan (1965)
 - Breslow (1970)
- The test statistics can also be formulated as No this ni, reduce to by-rank test

$$W = \sum_{i=1}^{k} \frac{n_i}{n_i} (d_{0i} - e_{0i})$$

- Weighted by n_i , the total number of subjects at risk at $t_{(i)}^-$ give more weights to early events
- The variance

$$var(W) = var\left(\sum_{i=1}^{k} n_i(d_{0i} - e_{0i})\right) = \sum_{i=1}^{k} \frac{n_{0i}n_{1i}d_i(n_i - d_i)}{(n_i - 1)}$$

A weighted log-rank test

General Class of Weighted Log-rank Tests

Can be written as

$$L_w = \sum_{i=1}^k \omega_i (d_{0i} - e_{0i})$$

$$var(L_w) = \sum_{i=1}^k \omega_i^2 \frac{n_{0i} n_{1i} d_i (n_i - d_i)}{n_i^2 (n_i - 1)}$$

| Test | Weight ω_i | |
|--------------------|--------------------------------------|-------------------|
| Log-rank | $\omega_i = 1$ | |
| Gehan's Wilcoxon | $\omega_i = n_i$ | |
| Peto/Prentice | $\omega_i = S(t_i)$ | A |
| Fleming-Harrington | $\omega_i = S(t_i)^p D S(t_{i-1})^p$ | (1-Scti-1) & pazo |
| Tarone-Ware | $\omega_i = \sqrt{n_i}$ | |

Comparisons

- All tests will control type I error under null
- May obtain optimal power under certain alternatives
- The Log-rank test
 - Tends to be sensitive to distributional differences which are separated late in time
 - Has the optimal power when the hazard ratio is constant
- The Wilcoxon test
 - Tends to be more powerful in detecting early separation between survival functions

can always derived one-side tese

Stratified Log-rank Test

- When comparing 2 groups, it is desirable to test between group within certain subgroups formed by factors such as
 - Disease severity Severe ↑ # of event 1
- The reason is that the background risk (in the control group) among the different factors are different
 - The risk in the mild patient population is different from that in the severe population
- The stratification factor for disease severity
 - Mild
 - Moderate
 - Severe

Stratified Log-rank Test

- Let s = 1, 2, ..., S be the stratum for a factor
- $h_{0s}(t)$ is the hazard of the s stratum in the control group

$$h_{0i}(t) \neq h_{0j}(t)$$
 for $i \neq j i, j = 1, 2, ..., s$

Assume the same treatment effect

$$\lambda = \frac{h_{1s}(t)}{h_{0s}(t)}$$

- The stratified log-rank test
 - Compares treatment effect between groups within each stratum first
 - Combine the comparisons of all strata

2x2 Table at the i^{th} Event Time in Stratum s

| Group | Events occurred at $t_{(i)}$ | Number of subjects Survival at $t_{(i)}^+$ | Number of subject at risk at $t_{(i)}^-$ |
|-------|------------------------------|--|--|
| 0 | d_{s0i} | $n_{s0i} - d_{s0i}$ | n_{s0i} |
| 1 | d_{s1i} | $n_{s1i} - d_{s1i}$ | n_{s1i} |
| Total | d_{si} | $n_{si}-d_{si}$ | n_{si} |

Stratified Log-rank Test

• Log-rank statistics in Stratum s, r'_s distinct survival time in Stratum s

$$L_s = \sum_{i=1}^{r_{s}} (d_{s0i} - e_{s0i})$$

$$var(L_s) = \sum_{i=1}^{r_{s}} \frac{n_{0i}n_{1i}d_{i}(n_{i}-d_{i})}{n_{i}^{2}(n_{i}-1)}$$

• The stratified log-rank test is

$$LS = rac{\sum_{S=1}^{S} L_S}{\sqrt{\sum_{S=1}^{S} var(L_S)}}$$
 each stratum are independent

Example – Ovarian Data

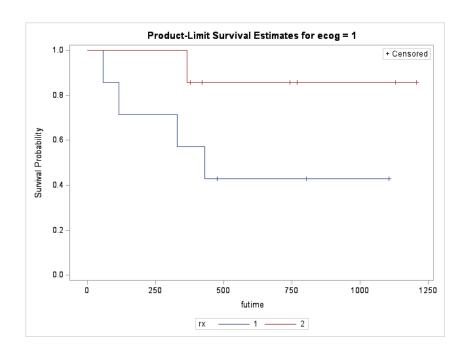

| | | fustat | | resid.ds | | |
|----|------|--------|---------|----------|---|-------------|
| 1 | 59 | 1 | 72.3315 | 2 | 1 | 1 |
| 2 | 115 | 1 | 74.4932 | 2 | 1 | 1 |
| 3 | 156 | 1 | 66.4658 | 2 | 1 | 2 |
| 4 | 421 | 0 | 53.3644 | 2 | 2 | 1 |

Comparison of Three or More Groups

- May consider evaluate survival functions of K independent samples: $S_0(t), S_1(t), \cdots, S_K(t)$
 - K-1 groups in comparison with one control group
 - From *K* country
- The null hypothesis is that all the K survival functions are the same

$$H_0: S_1(t) = S_2(t) = \cdots = S_K(t)$$

 $H_A: not(S_1(t) = S_2(t) = \cdots = S_K(t))$

- Group *k*
 - n_k number of subjects in Group k
 - (T_{k1},δ_{k1}) , (T,δ_{k2}) , ..., (T_{kn_k},δ_{kn_k}) are observed survival data in Group k
 - k = 1, ..., K
- Number of events in *K* groups: *r*
 - Ordered distinct event time: $t_{(1)} < t_{(2)} < \cdots < t_{(r')}$
 - $r' \leq r$

K x2 Table at the i^{th} Event Time

| Group | Events occurred at $t_{(i)}$ | Number of subjects Survival at $t_{(i)}^+$ | Number of subject at risk at $t_{(i)}^{-}$ |
|-------|------------------------------|--|--|
| 1 | d_{1i} | $n_{1i} - d_{1i}$ | n_{1i} |
| 2 | d_{2i} | $n_{2i}-d_{2i}$ | n_{2i} |
| | | | |
| K | d_{Ki} | $n_{Ki}-d_{Ki}$ | n_{Ki} |
| Total | d_i | $n_i - d_i$ | n_i |

At The *i*th Event Time

• Let

$$O_{i} = \begin{pmatrix} d_{1i} \\ \vdots \\ d_{Ki} \end{pmatrix}, \qquad E_{i} = \begin{pmatrix} n_{1i} \\ \vdots \\ n_{Ki} \end{pmatrix} \frac{d_{i}}{n_{i}}, \quad V_{i} = \begin{pmatrix} v_{11i} & v_{12i} & \dots & v_{1Ki} \\ & v_{22i} & \dots & v_{2Ki} \\ & & \dots & & & & & \\ & & & v_{2Ki} \end{pmatrix}$$

The test statistics can be written as

$$(O_i - E_i)'V_i^{-1}(O_i - E_i) \sim \chi^2(K)$$

- Omnibus test
 - To test if there is any difference among the survival functions
 - Not for pairwise comparisons
 - · Not powerful to detect trend

Trend Log-rank Tests

- Let us assume there is a trend among the (K + 1) independent samples
 - *K* different doses
 - Possible to have monotone dose-response relationship
- A trend test is to test the hypothesis against a specific alternatives

$$H_0$$
: $S_1(t) = S_2(t) = \cdots = S_K(t)$

$$H_A$$
: $S_1(t) \le S_2(t) \le \cdots \le S_K(t)$

Trend Log-rank Tests

• Log-rank statistics Kth dose

$$L_k = \sum_{i=1}^{r_{i_k}} (d_{0i} - e_{ki})$$

$$\operatorname{var}(L_k) = \sum_{i=1}^{r_{ik}} \frac{n_{0i} n_{ki} d_{ki} (n_{0ki} - d_{0ki})}{n_{0ki}^2 (n_{0ki} - 1)}$$

• The trend log-rank test is

$$LS = \frac{\sum_{k=1}^{K} \omega_k L_k}{\sqrt{\sum_{k=1}^{K} (\omega_k - \overline{\omega})^2 var(L_k)}} \sim \chi_1^2$$

$$\overline{\omega} = \frac{\sum_{k=1}^{K} \omega_k e_k}{\sum_{k=1}^{K} e_k}$$

where ω_k is a weight for dose k

Trend Tests

- How to choose weight ω_k
- For monotone relationship

$$\omega_k = k \text{ for } k = 1, ..., K$$

- When K=3
 - $\omega_1 = 1, \omega_2 = 2, \omega_3 = 3$
 - $\omega_1 = -1, \omega_2 = 0, \omega_3 = 1$

Homework 4

- 1. Using the Leukemia data
 - Group 0: 6+,6,6,6,7,9+,10+,10,11+,13,16,17+,19+,20+,22,23,25+,32+,32+,34+,35+
 - Group 1: 1,1,2,2,3,4,4,5,5,8,8,8,8,11,11,12,12,15,17,22,23
 - 16 Distinct event time: 1, 2, 3, 4, 5, 6, 7, 8, 10, 11, 12, 15, 16, 17, 22, 23
 - a) Construct the 16 2x2 tables for the log-rank test
 - b) Verify the rank statistics by calculating the difference of the observed and expected in each 2x2 tables

$$L = \sum_{i=1}^{k} (d_{0i} - e_{0i}) = -10.25$$

c) Include the variance calculation for each of the 2x2 tables as well and verify that

$$var(L) = \sum_{i=1}^{k} \frac{n_{0i}n_{1i}d_i(n_i - d_i)}{n_i^2(n_i - 1)} = 6.26$$

- 2. Outline steps how you would show the following using simulation (no actual simulation is required)
 - a) The Wilcoxon has the optimal power when the failure times are log-normally distributed, with equal variance in both groups but different means.
 - b) With weights $\omega_i = S(t_i)$, the test is most powerful under the alternative hypothesis of log-logistic model
- 3. Results from a trial evaluating a new treatment in comparison with a standard of care (SOC) indicate that biomark+ subgroup will have positive survival benefit with the new treatment and biomarker- subgroup actually gets harm.
 - a) Please discuss what you think of an analysis by including all subject?
 - b) How would you recommend the analysis?
 - c) Do you think if FDA should approve this drug?
